Chapter 1

- **.java file**  The source code of a Java program. It may contain one or more Java classes and interfaces. A .java file can be created using a text editor or a Java IDE such as NetBeans, Eclipse, and JBuilder.
- **.class file**  The output of the Java compiler. A .class file contains the byte code for the class.
- **assembly language**  A low-level programming language in which a mnemonic is used to represent each of the machine language instructions.
- **binary numbers**  Numbers consist of 0’s and 1’s.
- **block**  A sequence of statements enclosed in braces ({}).
- **byte**  A unit of storage. Each byte consists of 8 bits. The size of hard disk and memory is measured in bytes. A megabyte is roughly a million bytes.
- **bytecode**  The result of compiling Java source code. Bytecode is machine-independent and can run on any machine that has a Java running environment.
- **Bytecode verifier**  A program in the JVM that checks the validity of the bytecode and ensure that the bytecode does not violate Java’s security restrictions.
- **cable modem**  Uses the TV cable line maintained by the cable company. A cable modem is as fast as a DSL.
- **central processing unit (CPU)**  A small silicon semiconductor chip with millions of transistors that executes instructions.
- **class loader**  When executing a Java program, the JVM first loads the bytecode of the class to memory using a program called the class loader. If your program uses other classes, the class loader dynamically loads them just before they are needed.
- **comment**  Comments document what a program is and how it is constructed. They are not programming statements and are ignored by the compiler. In Java, comments are preceded by two slashes (//) in a line or enclosed between /* and */ in multiple lines.
- **compiler**  A software program that translates source code (e.g., Java source code) into a machine language program.
- **dot pitch**  The amount of space between pixels. The smaller the dot pitch, the better the display.
• **DSL (digital subscriber line)** Uses a phone line and can transfer data in a speed 20 times faster than a regular modem.

• **hardware** The physical aspect of the computer that can be seen.

• **hexadecimal numbers** Numbers with radix 16.

• **high-level programming language** Are English-like and easy to learn and program.

• **Integrated Development Environment (IDE)** Software that helps programmers write code efficiently. IDE tools integrate editing, compiling, building, debugging, and online help in one graphical user interface.

• **interpreter** Software for interpreting and running Java bytecode.

• **java** The command to invoke the interpreter to run a Java program from the command line.

• **javac** The command to invoke the compiler to compile a Java source code program from the command line.

• **Java Development Toolkit (JDK)** Defines the Java API and contains a set of command-line utilities, such as javac (compiler) and java (interpreter). With Java 2, Sun renamed JDK 1.5 to Java 2 SDK v 1.5. SDK stands for Software Development Toolkit.

• **Java Virtual Machine (JVM)** A machine that run Java byte-code. It is called virtual because it is usually implemented in software rather than in hardware.

• **Just-in-Time compiler** Capable of compiling each bytecode once, and then reinvoking the compiled code repeatedly when the bytecode is executed.

• **keyword (or reserved word)** A word defined as part of Java language, which have a specific meaning to the compiler and cannot be used for other purposes in the program.

• **machine language** Is a set of primitive instructions built into every computer. The instructions are in the form of binary code, so you have to enter binary codes for various instructions.

• **main class** A class that contains a main method.

• **memory** Stores data and program instructions for CPU to execute.

• **modem** A regular modem uses a phone line and can transfer data in a speed up to 56,000 bps (bits per second).

• **network interface card (NIC)** A device to connect a computer to a local area network (LAN). The LAN is commonly used in business, universities, and government.
organizations. A typical type of NIC, called 10BaseT, can transfer data at 10 Mbps.

- **operating system (OS)** A program that manages and controls a computer’s activities (e.g., Windows, Linux, Solaris).
- **pixel** Tiny dots that form an image on the screen.
- **resolution** Specifies the number of pixels per square inch. The higher the resolution, the sharper and clearer the image is.
- **software** The invisible instructions that control the hardware and make it work.
- **source code** A program written in a programming language such as Java.
- **source file** A file that stores the source code.
- **storage devices** The permanent storage for data and programs. Memory is volatile, because information is lost when the power is off. Program and data are stored on secondary storage and moved to memory when the computer actually uses them.
- **statement** A unit of code that represents an action or a sequence of actions.

**Chapter 2**

- **algorithm** Statements that describe how a problem is solved in terms of the actions to be executed, and specifies the order in which these actions should be executed. Algorithms can help the programmer plan a program before writing it in a programming language.
- **assignment operator** (=) Assigns a value to a variable.
- **assignment statement** A simple statement that assigns a value to a variable using an assignment operator (=). When a value is assigned to a variable, it replaces the previous value of the variable, which is destroyed.
- **backslash** (\) -- A character that precedes another character to denote the following character has a special meaning. For example, ‘\t’ denote a tab character. The backslash character is also used to denote a Unicode character like ‘\u00FF’.
- **bit** A binary digit 0 or 1.
- **byte type** A primitive data type that represents an integer in a byte. The range a byte value is from $-2^7$ (-128) to $2^7-1$ (127).
- **casting** The process of converting a primitive data type value into another primitive type.
- **char type** -- A primitive data type that represents a Unicode character.
- **constant** A variable declared final in Java. A local constant is a constant declared inside a method.
- **data type** Used to define variables to indicate what kind of value the variable can hold.
- **debugger** A program that facilitates debugging. It enables the program to be executed one statement at a time and enables the contents of the variable to be examined during execution.
- **debugging** The process of finding and fixing errors in a program.
- **declaration** Defines variables, methods, and classes in a program.
- **decrement operator** (--) Subtracts one from a numeric variable or a char variable.
- **double type** A primitive data type to represent double precision floating-point numbers with 14 to 15 significant digits of accuracy.
- **encoding** Representing a character using a binary code.
- **final** A modifier that specifies a constant.
- **float type** A primitive data type to represent single precision floating-point numbers with 6 to 7 significant digits of accuracy. The double type is used to represent double precisions with 14 to 15 significant digits of accuracy.
- **floating-point number** A number that includes a fractional part.
- **expression** Represents a computation involving values, variables, and operators, which evaluates to a value.
- **Expression statement** If an expression is used as a statement, it is called an expression statement.
- **identifier** A name of a variable, method, class, interface, or package.
- **increment operator** (++) Adds one to a numeric variable or a char variable.
- **incremental development and testing** A programming methodology that develop and test program incrementally. This approach is efficient and productive. It help eliminate and isolate errors.
- **indentation** The use of tabs and spaces to indent the source code to make it easy to read and understand.
- **int type** A primitive data type to represent an integer in the range from $-2^{31}$ (-2147483648) to $2^{31}-1$ (2147483647).
• **literal** A constant value that appears directly in the program. A literal may be numeric, character, boolean, or null for object type.

• **local variable** A variable defined inside a method. An initial value must be assigned to a local variable before it is referenced.

• **logic error** An error that causes the program to produce incorrect result.

• **long type** A primitive data type to represent an integer in the range from \(-2^{63}\) to \(2^{63-1}\).

• **narrowing (of types)** Casting a variable of a type with a larger range to a variable of a type with a smaller range.

• **operator** Operations for primitive data type values. Examples of operators are +, -, *, /, and %.

• **primitive data type** The primitive data types are byte, short, int, long, float, double, boolean, and char.

• **runtime error** An error that causes the program to terminate abnormally.

• **short type** A primitive data type that represents an integer in the range from \(-2^{15}\) (-32768) to \(2^{15-1}\) (32767).

• **syntax error** An error in the program that violates syntax rules of the language.

• **supplementary Unicode** The original Unicode is 16-bit. Those characters that go beyond the original 16-bit limit are called supplementary characters.

• **Unicode** A code system for international characters managed by the Unicode Consortium. Java supports Unicode.

• **Unix epoch** January 1, 1970 GMT is known as the Unix epoch because 1970 was the year when the Unix operating system was formally introduced.

• **variable** Variables are used to store data and computational results in the program.

• **widening (of types)** Casting a variable of a type with a smaller range to a variable of a type with a larger range.

• **whitespace** Characters ' ', '	', '', '', and '
' are whitespaces characters.
Chapter 3

- **boolean expression**  An expression that evaluates to a Boolean value.
- **boolean value**  true or false.
- **boolean type**  A primitive data type for Boolean values (true or false).
- **break statement**  Break out of the switch statement.
- **conditional operator**  The symbols ? and : appear together in a conditional expression: `booleanExpression ? expression1 : expression2;`
- **fall-through behavior**  In a switch statement, if once a case is matched, the statements starting from the matched case are executed until a break statement or the end of the switch statement is reached. This phenomenon is referred to as the fall-through behavior.
- **operand evaluation order**  Defines the order in which individual operands are evaluated.
- **operator associativity**  Defines the order in which operators will be evaluated in an expression if the operators have the same precedence order.
- **operator precedence**  Defines the order in which operators will be evaluated in an expression.
- **selection statement**  A statement that uses if or switch statement to control the execution of the program.
- **short-circuit evaluation**  Evaluation that stops when the result of the expression has been determined, even if not all the operands are evaluated. The evaluation involving && or || are examples of short-circuit evaluation.

Chapter 4

- **break statement**  Break out of the current loop.
- **continue statement**  Break out of the current iteration.
- **infinite loop**  A loop that runs indefinitely due to a bug in the loop.
- **iteration**  One time execution of the loop body.
- **labeled break statement**  Break out of the specified labeled loop.
- **labeled continue statement**  Break out of the current iteration of the labeled loop.
- **loop**  A structure that controls repeated executions of a block of statements.
- **loop-continuation-condition**  A Boolean expression
that controls the execution of the body. After each iteration, the loop-continuation-condition is reevaluated. If the condition is true, the execution of the loop body is repeated. If the condition is false, the loop terminates.

- **loop body** The part of the loop that contains the statements to be repeated.
- **nested loop** Consists of an outer loop and one or more inner loops. Each time the outer loop is repeated, the inner loops are reentered, and all required iterations are performed.
- **off-by-one error** A common in the loop because the loop is executed one more or one less time than it should have been.
- **sentinel value** A special input value that signifies the end of the input.

**Chapter 5**

- **actual parameter** (i.e., argument) The variables or data to substitute formal parameters when invoking a method.
- **argument** Same as actual parameter
- **ambiguous invocation** There are two or more possible methods to match an invocation of a method, neither is more specific than the other(s). Therefore, the invocation is ambiguous.
- **divide and conquer** The concept of method abstraction can be applied to the process of developing programs. When writing a large program, you can use the “divide and conquer” strategy to decompose it into subproblems. The subproblems can be further decomposed into smaller, more manageable problems.
- **formal parameter** (i.e., parameter) The variables defined in the method signature.
- **information hiding** A software engineering concept for hiding the detail implementation of a method for the client.
- **method** A collection of statements grouped together to perform an operation. See class method; instance method.
- **method abstraction** A technique in software development that hides detailed implementation. Method abstraction is defined as separating the use of a method from its implementation. The client can use a method without knowing how it is implemented. If you decide to change the implementation, the client program
Method overloading means that you can define methods with the same name in a class as long as there is enough difference in their parameter profiles.

- **method overloading**
- **method signature**
- **modifier**
- **package**
- **pass-by-value**
- **return type**
- **return value**
- **scope of variable**
- **stepwise refinement**
- **stub**

**Chapter 6**

- **anonymous array**
- **array**
- **array initializer**
- **binary search**
- **garbage collection**

© Copyright Y. Daniel Liang, 1997-2007
objects.

- **index** An integer value used to specify the position of an element in the array. The array index is an int value starting with 0 for the first element, 1 for the second, and so on.

- **indexed variable** arrayRefVar[index] is referred to as an indexed variable that access an element in the array through an index.

- **insertion sort** An approach to sort array. Suppose that you want to sort a list in ascending order. The insertion-sort algorithm sorts a list of values by repeatedly inserting a new element into a sorted sublist until the whole list is sorted.

- **linear search** A method to search an element in an array. Linear search compares the key with the element in the array sequentially.

- **multidimensional array** An array with more than one dimension.

- **ragged array** A multi-dimensional array with different length in the subarrays.

- **selection sort** An approach to sort array. It finds the largest number in the list and places it last. It then finds the largest number remaining and places it next to last, and so on until the list contains only a single number.

Chapter 7

- **accessor method** *(getter)* The method for retrieving a private field in an object.

- **class** An encapsulated collection of data and methods that operate on data. A class may be instantiated to create an object that is an instance of the class.

- **class abstraction** A technique in software development that hides detailed implementation. Class abstraction hides the implementation of the class from the client, if you decide to change the implementation, the client program will not be affected.

- **class encapsulation** Combining of methods and data into a single data structure.

- **class’s contract** Refers to the collection of methods and fields that are accessible from outside a class, together with the description of how these members are expected to behave.

- **composition** An object consists of other objects. This is called composition.
• **constant** A variable declared final in Java. Since a class constant is usually shared by all objects of the same class, a class constant is often declared static. A local constant is a constant declared inside a method.

• **constructor** A special method for initializing objects when creating objects using the new operator. The constructor has exactly the same name as its defining class. Constructors can be overloaded, making it easier to construct objects with different initial data values.

• **data field encapsulation** To prevent direct modifications of properties through the object reference, you can declare the field private, using the private modifier. Data field encapsulation makes the class easy to maintain.

• **default constructor** If a class does not define any constructors explicitly, a no-arg constructor with empty body is assumed. This is called a default constructor.

• **dot operator** (.) An operator used to access members of an object. If the member is static, it can be accessed through the class name using the dot operator.

• **immutable class** A class is immutable if it contains all private data fields and no mutator methods and no accessor methods that would return a reference to a mutable data field object.

• **instance** An object of a class.

• **instance method** A nonstatic method in a class. Instance methods belong to instances and can only be invoked by them.

• **instance variable** A nonstatic data member of a class. An instance variable belongs to an instance of the class.

• **instantiation** The process of creating an object of a class.

• **mutator method (setter)** A method that changes the value of a private field in an object.

• **null** A literal of a reference variable that does not reference any concrete object.

• **no-arg constructor** A constructor without arguments.

• **object-oriented programming (OOP)** An approach to programming that involves organizing objects and their behavior into classes of reusable components.

• **Unified Modeling Language (UML)** A graphical notation for describing classes and their relationships.
• **package-private** (or **package-access**). If public or private is not used, then by default the classes, methods, and data are accessible by any class in the same package. This is known as package-private or package-access.

• **private**. A modifier for members of a class. A private member can only be referenced inside the class.

• **public**. A modifier for classes, data, and methods that can be accessed by all programs.

• **reference**. A value that references an object.

• **reference type**. A data type that is a class or an interface.

• **stack**. A stack is a data structure that holds objects in a last-in first-out fashion.

• **static method**. A method that can be invoked without creating an instance of the class. To define static methods, put the modifier static in the method declaration.

• **static variable**. A data member declared using the static modifier. A static variable is shared by all instances of that class. Static variables are used to communicate between different objects of the same class and to handle global states among these objects.

• **this**. Refers to the object itself.

---

**Chapter 8**

• **interned string**. Since strings are immutable and are frequently used, to improve efficiency and save memory, the JVM uses a unique instance for string literals with the same character sequence. Such an instance is called interned.

• **regular expression** (abbreviated regex) is a string that describes a pattern for matching a set of strings.

---

**Chapter 9**

• **array list**. A data structure for storing a list of array. The list size can grow and shrink.

• **casting objects**. Converting an object of one object type into another object type. The contents of the object are not changed.

• **constructor chaining**. Constructing an instance of a class invokes all the constructor, chaining superclasses along the inheritance chain.
• dynamic binding A method may be defined in a superclass, but is overridden in a subclass. Which implementation of the method is used on a particular call will be determined dynamically by the JVM at runtime. This capability is known as dynamic binding.

• final A modifier for classes, data, methods, and local variables. A final class cannot be extended, a final data or local variable is a constant, and a final method cannot be overridden in a subclass.

• generic programming Allows methods to be used generically for a wide range of object arguments through polymorphism.

• inheritance Declaring a new class by extending an existing class.

• initialization block A block of statements that appears in the class declaration, not inside a method. A non-static initialization block is executed as if it were placed at the beginning of every constructor in the class. A static initialization block is executed when the class is loaded.

• instanceof An operator that checks whether an object is an instance of a class.

• is-a relationship Same as inheritance.

• meta-object An object of java.lang.Class. When a class is loaded, the JVM creates an object that contains the information about the class.

• override Implement the method in a subclass that is declared in a superclass.

• polymorphism Refers to the feature that an object of a subclass can be used by any code designed to work with an object of its superclass.

• protected A modifier for members of a class. A protected member of a class can be used in the class in which it is declared or any subclass derived from that class.

• subclass (child class or derived class) A class that inherits from or extends a superclass.

• subtype Same as subclass.

• superclass (parent class or extended class) A class inherited from a subclass.

• supertype Same as superclass.

• vector Similar to array list except that the update methods are synchronized in a vector.
Chapter 10

- **abstract class** When you are designing classes, a superclass should contain common features that are shared by subclasses. Sometimes the superclass is so abstract that it cannot have any specific instances. These classes are called abstract classes and are declared using the abstract modifier. Abstract classes are like regular classes with data and methods, but you cannot create instances of abstract classes using the new operator.

- **abstract method** A method signature without implementation. Its implementation is provided by its subclasses. An abstract method is denoted with an abstract modifier and must be contained in an abstract class. In a nonabstract subclass extended from an abstract class, all abstract methods must be implemented, even if they are not used in the subclass.

- **deep copy** When cloning an object, all its fields are cloned recursively.

- **interface** An interface is treated like a special class in Java. Each interface is compiled into a separate bytecode file, just like a regular class. You cannot create an instance for an interface. The structure of a Java interface is similar to that of an abstract class in that it can have data and methods. The data, however, must be constants, and the methods can have only declarations without implementation. Single inheritance is the Java restriction wherein a class can inherit from a single superclass. This restriction is eased by the use of an interface.

- **marker interface** An empty interface that is used to signify that all the classes implementing the interface share certain properties.

- **multiple inheritance** A class may extend multiple superclasses.

- **shallow copy** When cloning an object, all its fields are copied.

- **single inheritance** A class can extend only one superclass.

- **subinterface** An interface inherited from other interface.

- **wrapper class** A class that provides an object representation for primitive data type values. Java provides wrapper classes **Byte**, **Short**, **Integer**, **Long**, **Float**, **Double**, **Character**, and **Boolean** for primitive data types **byte**, **short**, **int**, **long**, **float**, **double**, **char**, **boolean**.
and `boolean`.

Chapter 11

- **aggregation** A special form of association that represents an ownership relationship between two classes.
- **Application Program Interface (API)** A set of classes and interfaces that can be used to develop Java programs.
- **association** A general binary relationship that describes an activity between two classes.
- **composition** A form of relationship that represents exclusive ownership of the class by the aggregated class.
- **dependency** A dependency describes a relationship between two classes where one (called client) uses the other (called supplier).
- **framework-based programming** A software development methodology for developing applications based on the framework of reusable classes and interfaces.
- **sequence diagram** A UML diagram that describes interactions among objects by depicting the time-ordering of method invocations.
- **statechart** A UML diagram that describes the flow of control of an object.

Chapter 12

- **Abstract Window Toolkit (AWT)** The set of components for developing simple graphics applications that was in use before the introduction of Swing components. The AWT user interface components have now been replaced by the Swing components, but other AWT classes such as helper classes, and event-handling classes are still used.
- **heavyweight component** Rendering of the GUI components are heavily dependent on the native GUI.
- **lightweight component** Rendering of most of the GUI components are independent on the native GUI.
- **Swing** The Swing GUI components are painted directly on canvases using Java code except for components that are subclasses of `java.awt.Window` or `java.awt.Panel`, which must be drawn using native GUI on a specific platform. Swing components are less dependent on the target platform and use less resource of the native GUI. Swing components are more flexible and versatile.
than their AWT counterparts.

Chapter 14

- **anonymous inner class** An inner class without a name.
- **convenience listener adapter** A class that implements all the methods in a listener interface with an empty body.
- **event** A signal to the program that something has happened. Events are generated by external user actions, such as mouse movements, mouse button clicks, and keystrokes, or by the operating system, such as a timer. The program can choose to respond to an event or to ignore it.
- **event delegation** In Java event-driven programming, events are assigned to the listener object for processing. This is referred to as event delegation.
- **event handler** A method in the listener's object that is designed to do some specified processing when a particular event occurs.
- **event listener** The object that receives and handles the event.
- **event listener interface** An interface implemented by the listener class to handle the specified events.
- **event object** Contains whatever properties are pertinent to the event.
- **event registration** To become a listener, an object must be registered as a listener by the source object. The source object maintains a list of listeners and notifies all the registered listeners when an event occurs.
- **event source (source object)** The object that generates the event.
- **event-driven programming** Java graphics programming is event-driven. In event-driven programming, codes are executed upon the activation of events, such as clicking a button or moving the mouse.
- **inner class** A class embedded in another class. Inner classes enable you to define small auxiliary objects and pass units of behavior, thus making programs simple and concise.

Chapter 16

- **applet** A special kind of Java program that can run directly from a Web browser. Various security restrictions are imposed on applets. For example, they
cannot perform input/output operations on a user's system and therefore cannot read or write files or transmit computer viruses.

- **HTML (Hypertext Markup Language)**  A script language to design Web pages for creating and sharing multimedia-enabled, integrated electronic documents over the Internet.
- **.html or .htm file**  The source code of an HTML file. It contains HTML tags and text. It is the input for a Web browser. A Web browser displays the contents of a .html or .htm file.
- **tag**  An HTML instruction that tells a Web browser how to display a document. Tags are enclosed in brackets, such as `<html>`, `<i>`, `<b>`, and `</html>`.
- **JAR**  Java archive file can be used to group all the project files in a compressed file for deployment.

**Chapter 17**

- **assertion**  A Java statement that enables you to assert an assumption about your program. An assertion contains a Boolean expression that should be true during program execution. Assertions can be used to ensure program correctness.
- **checked exception**  Exceptions other than `RuntimeException` and `Error`.
- **exception**  An unexpected event indicating that a program has failed in some way. Exceptions are represented by exception objects in Java. Exceptions can be handled in a `try-catch` block.
- **unchecked exception**  Instances of `RuntimeException` and `Error`.

**Chapter 18**

- **binary I/O**  Binary I/O interprets data as raw binary values.
- **deserialization**  The process of restoring an object that was previously serialized.
- **file pointer**  A location marker in a random access file where data is read and written.
- **random access file**  The file that can be both read and written in any order.
- **sequential access file**  The file is read or written sequentially from beginning to end.
- **serialization**  The process of writing an object to a stream.
• **stream**  A stream is an object that facilitates input or output. For input, it is called an input stream. For output, it is called an output stream.

• **text I/O**  Text I/O interprets data in sequences of characters.

Chapter 19

• **base case**  A simple case where recursion stops.

• **infinite recursion**  Recursion never stops.

• **recursive method**  A method that invokes itself directly or indirectly.

• **recursive helper method**  Sometimes the original method needs to be modified to receive additional parameters in order to be invoked recursively. A recursive helper method can be declared for this purpose.

• **stopping condition**  Same as base case.

Chapter 20

• **binary search tree**  A binary tree with no duplicate elements. For every node in the tree the value of any node in its left subtree is less than the value of the node and the value of any node in its right subtree is greater than the value of the node.

• **binary tree**  A data structure to support searching, sorting, inserting, and deleting data efficiently.

• **data structure**  A collection of data organized in some fashion. A data structure not only stores data, but also supports the operations for manipulating data in the structure.

• **dynamic data structure**  A data structure that grows and shrinks at runtime.

• **heap**  A binary tree with the following properties: It is a complete binary tree. Each node is greater than or equal to any of its children.

• **inorder traversal**  Visit the left subtree of the current node first, then the current node itself, and finally the right subtree of the current node.

• **list**  A collection of data stored sequentially. It supports insertion and deletion anywhere in the list.

• **object-oriented data structure**  In object-oriented thinking, a data structure is an object that stores other objects, referred to as data or elements. So some people refer an object-oriented data structure as a container object or a collection object.
• **postorder traversal**  Visit the left subtree of the current node first, then the right subtree of the current node, and finally the current node itself.

• **preorder traversal**  Visit the current node first, then the left subtree of the current node, and finally the right subtree of the current node.

• **queue**  Represents a waiting list, where insertions take place at the back (also referred to as the tail of) a queue and deletions take place from the front (also referred to as the head of) of a queue.

• **stack**  A special type of the list where insertions and deletions take place only at the one end, referred to as the top of a stack.

• **tree traversal**  A process of visiting each node in the tree exactly once.

Chapter 21

• **actual concrete type**  A concrete type that substitutes a generic type.

• **bounded generic type**  A generic type with a bound (e.g., `<E extends SomeClass>`).

• **formal generic type**  A generic type.

• **generic instantiation**  The process that instantiates a generic type with a concrete type.

• **raw type**  For backward compatibility, a generic class may be used without specifying a concrete class.

• `<?>` type  A wildcard that represents any object type.

• `<? extends E>` type  Bounded wildcard.

• `<? super E>` type  Lower bound wildcard.

Chapter 22

• **collection**  An object that contains a set or a list of objects.

• **comparator**  A collection of ordered elements with duplicates allowed.

• **hash map**  A map in which entries are stored in unpredictable order.

• **hash set**  A set in which elements are stored in unpredictable order.

• **linked hash map**  A map in which entries are stored in certain order (insertion order or access order).

• **linked hash set**  A map in which elements are stored in certain order (insertion order or access order).
• list A collection of ordered elements with duplicates allowed.
• map A collection of entries, each consists of a key and an object.
• priority queue In a priority queue, elements are assigned with priorities. When accessing elements, the element with the highest priority is removed first.
• queue A collection of entries, each consists of a key and an object.
• set A collection of nonduplicate elements.
• tree map A map in which the keys are sorted.
• tree set A set in which the elements are sorted.

Chapter 23

• average-case analysis An average-case analysis attempts to determine the average amount of time among all possible input of the same size.
• best-time analysis An input that results in the shortest execution time is called the best-case input. The analysis to find the best-case time is known as worst-time analysis.
• big O notation Comparing algorithms by examining their growth rates. This notation allows you to ignore constants and smaller terms while focusing on the dominating terms.
• bubble sort The bubble sort algorithm makes several passes through the array. On each pass, successive neighboring pairs are compared. If a pair is in decreasing order, its values are swapped; otherwise, the values remain unchanged. The technique is called a bubble sort or sinking sort because the smaller values gradually "bubble" their way to the top and the larger values sink to the bottom.
• constant time The Big $O$ notation estimates the execution time of an algorithm in relation to the input size. If the time is not related to the input size, the algorithm is said to take constant time with the notation $O(1)$.
• exponential time An algorithm with the $O(c^n)$ time complexity is called an exponential algorithm. As the input size increases, the time for the exponential algorithm grows exponentially. The exponential algorithms are not practical for large input size.
• growth rate measures how fast the time complexity of an algorithm grows as the input size grows.
• **heap sort**  Heap sort uses a binary heap to sort an array.

• **logarithmic time**  An algorithm with the $O(\log n)$ time complexity is called a logarithmic algorithm.

• **quadratic time**  An algorithm with the $O(n^2)$ time complexity is called a quadratic algorithm.

• **merge sort**  The merge sort algorithm can be described recursively as follows: The algorithm divides the array into two halves and applies merge sort on each half recursively. After the two halves are sorted, merge them.

• **quick sort**  Quick sort, developed by C. A. R. Hoare (1962), works as follows: The algorithm selects an element, called the pivot, in the array. Divide the array into two parts such that all the elements in the first part are less than or equal to the pivot and all the elements in the second part are greater than the pivot. Recursively apply the quick sort algorithm to the first part and then the second part.

• **worst-time analysis**  An input that results in the longest execution time is called the worst-case input. The analysis to find the worst-case time is known as worst-time analysis.

Chapter 24

• **condition**  A lock may create any number of Condition objects for thread communications.

• **deadlock**  A situation in which two or more threads acquire locks on multiple objects and each has the lock on one object and is waiting for the lock on the other object.

• **event dispatcher thread**  A designated thread for processing events in Java.

• **fail-fast**  Refers to iterators. If you are using an iterator to traverse a collection while the underlying collection is being modified by another thread, then the iterator will immediately fail by throwing java.util.ConcurrentModificationException, which is a subclass of RuntimeException.

• **fairness policy**  A parameter for a Lock. If fairness policy is true, it guarantees the longest-wait thread to obtain the lock first. False fairness policies grant a lock to a waiting thread without any access order. Programs using fair locks accessed by many threads may have poor overall performance than those using the
default setting, but have smaller variances in times to obtain locks and guarantee lack of starvation.

- **lock** To access mutual exclusive resource, you must first obtain an appropriate lock.
- **race condition** A situation that causes data corruption due to unsynchronized access of data by multiple threads.
- **synchronization wrapper** The Collections class provides six static methods for wrapping a collection into a synchronized version.
- **synchronized** A keyword to specify a synchronized method or a synchronized block. A synchronized instance method acquires a lock on this object and a synchronized static method acquires a lock on the class. A synchronized block acquires a lock on a specified object, not just this object before executing the statements in the block.
- **thread** A flow of execution of a task, with a beginning and an end, in a program. A thread must be an instance of java.lang.Thread.
- **thread-safe** A class is said to be thread-safe if an object of the class does not cause a race condition in the presence of multiple threads.

**Chapter 26**

- **locale** A mechanism that uniquely identifies resources on the Internet.
- **resource bundle** A Java class file or a text file that provides locale-specific information to be accessed by Java programs dynamically.
- **file encoding scheme** An encoding scheme specifies how text is stored in a file.

**Chapter 27**

- **event set** Event class and its corresponding listener interface consists of an event set.
- **JavaBeans component** A serializable public class with a public no-arg constructor.
- **JavaBeans events** A bean may have events with correctly constructed public registration and deregistration methods that enable the bean to add and remove listeners. If the bean plays a role as the source of events, it must provide registration methods for
registering listeners. By convention, the registration method is named `add<EventListener>(EventListener listener)` and a deregistration method is named `remove<EventListener>(EventListener listener)`.

- **JavaBeans properties**  A JavaBeans property is defined by its accessor or mutator methods, or both. By convention, the accessor method is named `get<PropertyName>()`, which takes no parameters and returns a primitive type value or an object of a type identical to the property type. For a property of boolean type, the accessor method should be named `is<PropertyName>()`, which returns a boolean value. The mutator method should be named `set<PropertyName>(dataType p)`, which takes a single parameter identical to the property type and returns void.

**Chapter 32**

- **database system**  consists of a database, the software that stores and manages data in the database, and the application programs that present data and enable the user to interact with the database system.

- **domain constraint**  specifies the permissible values for an attribute. Domains can be specified using standard data types, such as integers, floating-point numbers, fixed-length strings, and variant-length strings. The standard data type specifies a broad range of values.

- **foreign key constraint**  defines the relationships among relations. A foreign key is an attribute or a set of attributes in one relation that refers to the primary key in another relation.

- **integrity constraint**  imposes a condition that all legal values of the tables must satisfy. In general, there are three types of constraints: domain constraints, primary key constraints, and foreign key constraints. DBMS enforces integrity constraints and rejects any operation that would violate them.

- **primary key constraint**  specifies that the values of the primary key are unique in a relation.

- **relational database**  based on the relational data model. A relational database stores data in tables (also known as relations). A relational data model has three key components: structure, integrity, and languages. Structure defines the representation of the data. Integrity imposes constraints on the data. Language provides the means for accessing and manipulating data.
• **Structured Query Language (SQL)**  the language for defining tables and integrity constraints and for accessing and manipulating data.

**Chapter 30**

• **MVC architecture**  An approach for developing components by separating data storage and handling from the visual representation of the data.
• **model**  The component for storing and handling data, known as a model, contains the actual contents of the component.
• **view**  The component for presenting the data, known as a view, handles all essential component behaviors.
• **controller**  The controller is a component that is usually responsible for obtaining data.

**Chapter 33**

• **BLOB type**  a new SQL type defined in SQL3 for representing a binary large object (e.g., an image file, java objects).
• **CLOB type**  a new SQL type defined in SQL3 for representing a character large object (e.g., a large text file).
• **batch mode**  executing SQL statements in batch mode from JDBC.
• **scrollable result set**  You can scroll a result set in JDBC 2 and move the cursor in any direction or directly anywhere.
• **updateable result set**  You can update database through a result set in JDBC 2.

**Chapter 34**

• **Common Gateway Interface (CGI)**  A protocol for server-side programs to generate dynamic Web content.
• **CGI programs**  The programs that interact with a Web server through the common gateway interface. The Web server receives a request from a Web browser and passes it to the CGI program. The CGI program processes the request and generates a response at runtime. CGI programs can be written in any language, but the Perl language is the most popular choice.
• **Cookie**  Small text files that store sets of name-value pairs on the disk in the client’s computer. Cookies can be used for session tracking.

• **GET and POST methods** The methods for sending requests to the Web server. The POST method always triggers the execution of the corresponding CGI or servlet program. The GET method may not cause the CGI or servlet program to be executed if the previous same request is cached in the Web browser.

• **HTML form** An HTML construct that enables you to submit data to the Web server in a convenient form. When issuing a request from an HTML form, either a GET method or a POST method can be used. The form explicitly specifies which of the two is used. If the GET method is used, the data in the form are appended to the request string as if it were submitted using a URL. If the POST method is used, the data in the form are packaged as part of the request file. The server program obtains the data by reading the file.

• **life-cycle methods** Every servlet implements the Servlet interface. The `init`, `service`, and `destroy` methods are known as life-cycle methods in the Servlet interface.

• **URL query string** Part of URL that specifies the location of the servlet program, parameters, and their values (e.g., `ServletClass?pname1=pvalue1&pname2=pvalue2`). The `?` symbol separates the program from the parameters. The parameter name and value are associated using the `=` symbol. Parameter pairs are separated using the `&` symbol. The `+` symbol denotes a space character.

• **servlet** A Java program that runs on a Web server to produce dynamic Web pages.

• **servlet container (servlet engine)** A software that runs servlets.

• **Tomcat** A servlet engine developed by Apache that serves as a standard reference implementation for Java servlets and Java Server Pages. It can be used to test servlets and ServerPages.
